State of Global Water Resources 2021 by WMO

December 3, 2022

<u>In news</u>— WMO has published its first State of Global Water Resources report in order to assess the effects of climate, environmental and societal change on the Earth's water resources.

Key highlights of the report-

- The report gives an overview of river flow, as well as major floods and droughts.
- The aim of this annual stocktake is to support the monitoring and management of global freshwater resources in an era of growing demand and limited supplies.

• The report focusses on three major areas:

- 1. Streamflow, the volume of water flowing through a river channel at any given time.
- 2. Terrestrial water storage (TWS) all water on the land surface and in the sub-surface.
- 3. The cryosphere (frozen water).
- It provides insights into hotspots for changes in freshwater storage and highlights the crucial role and vulnerability of the cryosphere (snow and ice).
- It shows how large areas of the globe recorded drier than normal conditions in 2021 – a year in which precipitation patterns were influenced by climate change and a La Ninã event.
- The area with below-average streamflow was approximately two times larger than the above-average area, in comparison to the 30-year hydrological average.
- Currently, 3.6 billion people face inadequate access to water at least a month per year and this is expected to increase to more than 5 billion by 2050.
- Between 2001 and 2018, UN-Water reported that 74% of all

natural disasters were water-related.

- The recent UN climate change conference, COP27, urged governments to further integrate water into adaptation efforts, the first-time water has been referenced in a COP outcome document in recognition of its critical importance.
- The first edition of the report looks at streamflow the volume of water flowing through a river channel at any given time.
- It also assesses terrestrial water storage all water on the land surface and sub-surface and the cryosphere (frozen water).
- It highlights the lack of accessible verified hydrological data.
- WMO's Unified Data Policy seeks to accelerate the availability and sharing of hydrological data, including river discharge and transboundary river basins information.
- The information and accompanying maps are largely based on modelled data (to achieve maximum geographical coverage) and remotely sensed information from NASA's GRACE (Gravity Recovery and Climate Experiment) mission for terrestrial water storage.
- •WMO's Unified Data Policy seeks to accelerate the availability and sharing of hydrological data, including river discharge and transboundary river basins information.

What does the report say about the Indian subcontinent and Asia?

- According to the World Meteorological Organization (WMO), there is more evidence of the worsening impact of global warming on the Indo-Gangetic Plain (IGP) that straddles eastern Pakistan, northern India, southern Nepal and the whole of Bangladesh.
- The Ganga-Brahmaputra and Indus basins that form the

Plain, recorded more water flowing in the river channels due to glacial melt even as their total water storage declined in 2021.

- Southern and northern China (the Amur river basin) were characterized by above-average discharge, similar to some basins in northern India.
- In India, headwaters of the Ganges River were characterized by above- to much above-normal discharge.
- Major Indian river basins (the Brahmaputra, Ganges and Indus), as well as other important river basins in Asia (Huang He, also known as Yellow, and Mekong), exhibit a gradual decline in TWS over the period 2002-2021.
