## The Great Pacific Garbage Patch

April 19, 2023

<u>In news</u>— In a recent study, researchers from Canada, the Netherlands, and the U.S. have reported that coastal lifeforms have colonised plastic items in the Great Pacific Garbage Patch, throwing up many dubious firsts.

## **Key findings-**

- The tsunami off the Japanese coast in 2011 contributed to the debris in this garbage patch.
- Until at least 2017, researchers had found debris washing ashore on the West coast of North America containing live lifeforms originally found in Japan.
- From November 2018 to January 2019, researchers collected 105 pieces of plastic debris from the eastern part of the North Pacific Subtropical Gyre (NPSG), the most heavily plastic-polluted ocean gyre on the globe.
- Based on studying them, they reported that 98% of the debris items had invertebrate organisms.
- They also found that pelagic species (i.e. of the open ocean) were present on 94.3% of them and coastal species, on 70.5%. That is, organisms found on coasts were getting by on small floating islands of garbage (to humans) out in the Pacific Ocean.
- The number of coastal species such as arthropods and molluscs identified rafting on plastic was over threetimes greater than that of pelagic species that normally live in the open ocean.
- In all, they found organisms belonging to 46 taxa, and 37 of them were coastal; the rest were pelagic.
- Among both coastal and pelagic organisms, crustaceans were the most common.
- The coastal species were most commonly found on fishing

nets whereas the pelagic species, on crates.

- According to the paper, "Nearly all taxa were of Northwest Pacific origin", including Japan.
- •Similarly, most debris items (85.7%) did not have identifiable markings linked to origin, such as manufacture locations or company/brand names.
- However, eight of the remainder were from East Asia and five specifically from Japan. Four items were from North America.
- The researchers also found that 68% of the coastal taxa and 33% of the pelagic taxa reproduced asexually, and that there was evidence of sexual reproduction among the hydroids and the crustaceans, among others. They found a strong positive correlation between reproduction and mobility.

## What is the Great Pacific Garbage Patch?

- There are some water currents in the oceans that, driven by winds and the Coriolis force, form loops. These are called gyres.
- The North Pacific Subtropical Gyre (NPSG) is one such, located just north of the equator in the Pacific Ocean.
- It consists of the Kuroshio, North Pacific, California, and North Equatorial currents and moves in a clockwise direction.
- These currents flow adjacent to 51 Pacific Rim countries. Any trash that enters one of these currents, from any of these countries, could become part of the

gyre.

- Inside this gyre, just north of Hawai'i, lies a long east-west strip where some of the debris in these currents has collected over the years.
- The eastern part of this is the Great Pacific Garbage Patch. It is, as per one estimate, 1.6 million sq. km big and more than 50 years old.
- The patch contains an estimated 45,000-1,29,000 metric tonnes of plastic, predominantly in the form of microplastics.
- The numerical density of plastics here is around 4 particles per cubic metre.
- Mass-wise, however, heavier, more visible objects that haven't yet broken down into smaller particles accounted for 92% in 2018.
